

Fisheries Sampling and Data Collection

Steven Mackinson
Chief Scientific Officer, SPFA

Scientist for the Scottish Pelagic Fishermen's Association

Scottish pelagic fishermen, respected providers of scientifically credible data that's used to assess fish stocks, monitor changes in the pelagic ecosystem, and support management decisions.

3. Actively contribute to European and international developments of the science agenda influencing approaches to management of pelagic stocks.

4. Strengthen and promote collaborative science partnerships involving industry, government and academia.

5. Build awareness and understanding of the science concepts and issues relevant to pelagic industry, through engaging and informative media.

6. Uphold scientific standards and maintain scientific reputation at all times

1. Establish pelagic fishing vessels as research platforms, mapping changes in the abundance and distribution of pelagic fish in the areas they operate.

Equip and train in relevant technologies and methods to achieve 1.

2. Work with fish factories to promote the collection of scientific biological data on pelagic fish

Overview of this session

What information is needed and why

How it's collected - understanding different approaches to data collection and the methods used

How it's used

How can industry contribute?

What information is needed
and why?

Key information needs and its use

How many fish in the sea?

Setting fishing quotas and conservation measures.

How many get caught?

Estimating how many fish of each age group are in the sea and whether fishing pressure is sustainable.

The 'biology' - age, length and weight composition of the **population** and **catch**.

Where boats fish and how much (effort, catch per unit effort).

Translating goals for maintaining stocks in to the amount of fishing effort required for good average long-term catches. Indicators of the fishery performance and stock availability. Partitioning impacts by fleets.

Where fish are, where they go and why?

Fish migration and distribution patterns used in defining stocks, estimating abundance, fishing opportunities and spatial management measures.

How changes in the environment affect fish.

How changes in availability and productivity affect sustainable harvest rates and fishing opportunities.

Where does the information
come from and how is it
collected?

Data sources and the methods used to collect it

Fisheries Dependent

– meaning *information about catches and fishing activity* collected from the industry during the course of their normal operations.

Conducted as a requirement under statutory sampling programmes such as the EU Data Collection Framework (DCF) or for specific research programmes.

Includes catch and effort data plus biological data from landings.

Fisheries Independent

– meaning *information about the fish population and environment* collected during scientific surveys, using sampling designs that provide the best estimate of stock density.

Conducted as a statutory requirement (DCF) or to address specific research questions.

Includes survey catch and effort data plus a variety of biological, oceanographic and environmental data.

Fisheries dependent

Catch and fishing activity

Fishing position, time (VMS)

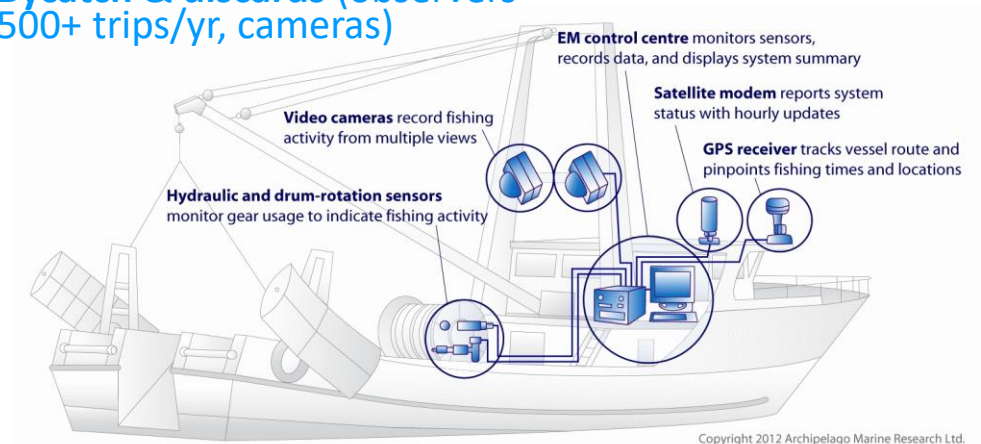

Catch records (logbook)

Vessels size/ power (registration)

Bycatch & discards (observers 500+ trips/yr, cameras)

Fisheries dependent

Biological data on catch

Routine - Length, weight, sex ratio, maturity stage.

Then age determination from ear bones (otoliths).

The End Game

How many fish of each age group were caught - for use in stock assessment

Catch numbers in millions (North Sea herring)

Year/rings	0	1	2	3	4	5	6	7	8	9+	Total
2003	369	617	1204	517	820	243	106	120	37	8	4042
2004	716	207	439	1326	520	726	171	101	71	22	4298

Fisheries dependent

Economic activity

HOW IS YOUR DATA USED?

1

FIELD RESEARCH

Seafish researchers visit ports around the country, interviewing fishing business owners and collecting consent to view accounts.

2

SEGMENTATION

Vessels are grouped into segments by length, capacity, gear type and fishing location.

3

FINANCIAL ACCOUNTS

Seafish economists contact accountants to collect copies of financial accounts from vessel owners who have given permission.

6

a) Individual benchmark reports are produced at vessel owners request for those who contributed accounts to the sample.

b) Data feeds into advice and reports for industry and policy makers.

REPORT PRODUCTION

5

DATA ANALYSIS

Aggregated data is analysed to estimate turnover, profit and expenses for all segments.

4

SCALING DATA

Anonymised accounts are used as samples and scaled up using MMO data, providing estimates for all UK vessels. Individual information is never released.

Fisheries independent

Survey catch

Environment

Biology

Oceanography

Fisheries independent - methods

Use

Monitor change in the density of fish over time and space – an indicator of change in population size. Tuning stock assessment models, where surveys used to provide the patterns over time and catches are used to give size of population.

Method principles

- Not trying to count all the fish, but not trying to avoid them either!
- Uses statistical sampling methods to make a best guess (most accurate estimate) of the fish population in the area.
- Standardized methods so that the density 'signal' doesn't get muddled and multiple surveys are comparable and can be combined.
- Trade-offs: tools (gear) and species suitability, accuracy and precision

The End Game

Abundance of each age group - for use in stock assessment (the survey 'numbers-at-age matrix').

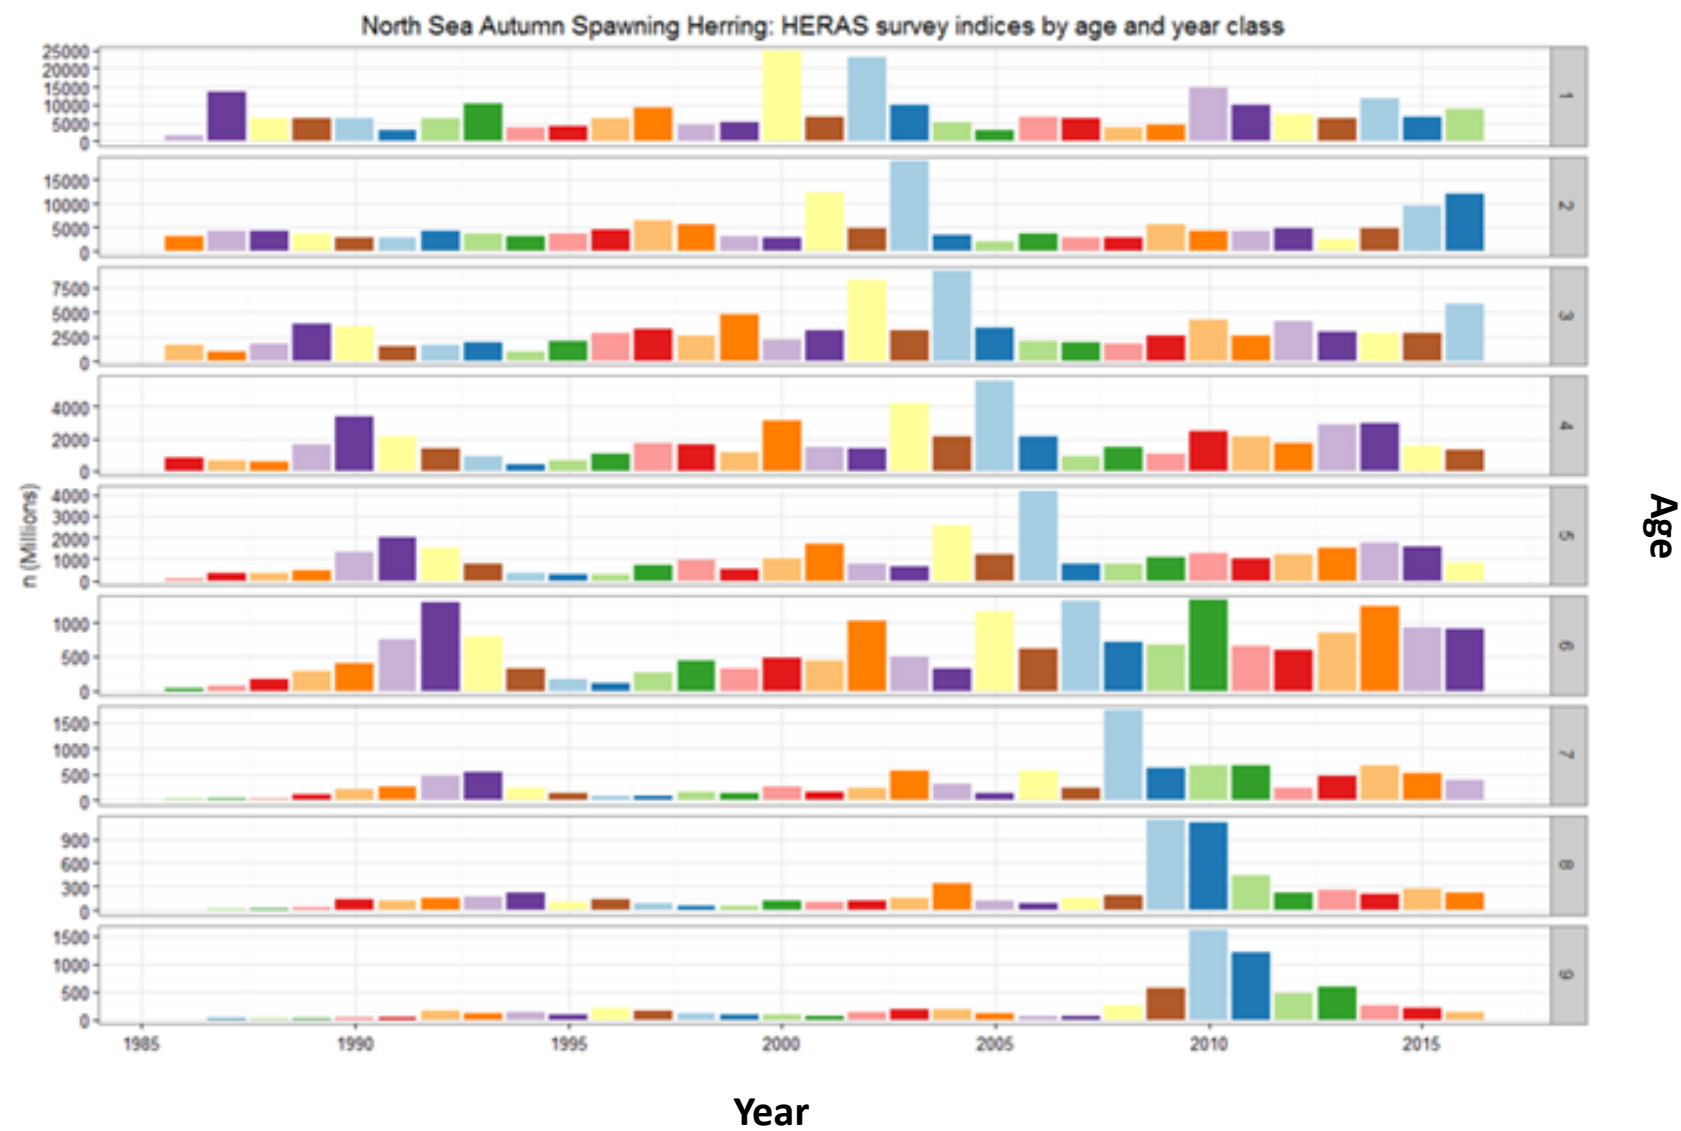

Swept area surveys

[International bottom trawl survey \(IBTS\)](#)

Numbers-at-age matrix

North Sea Herring Acoustic Survey. Time series of numbers-at-age at ages 1-9+. Colours indicate year-classes. All ages are scaled independently and therefore the size of the bars can only be compared within an age.

Common questions about swept area surveys

- Why do you fish in random locations when we know fish aren't random?
- Why use that old sock of a net? It couldn't catch squat.
- How can you tell us how many fish in the sea when you don't see any in your survey?

Numbers-at-age matrix: *surveys* and *catch*

Survey

2013 year class
'Recruits' (0-wr) in 2014

Catch

Age

Recruitment at age (wr) 0

Fisheries independent

Nephrops surveys

Use

Stock density in each functional unit

Survey Principles

- Swept area principle, where the sweeping is how many burrows per area of seabed

Tools

- Sledge mounted TV cameras
- Different ground types and 'functional units' are surveyed because burrow density varies

Method

- The TV goes down and records over a swept area.
- Someone watches TV and counts the burrows.
- Catch samples used to determine mean weight and sex ratios
- Numbers are converted to stock biomass
- Other organisations do the same and compare and combine

[Resource: How Nephrops surveys work](#)

Fisheries independent

Acoustic surveys

Use

Stock size and distribution. Behaviour and migration.

Survey Principles

- Not trying to count all the fish, but not trying to avoid them either
- Unbiased estimates of average density within the area surveyed

Tools

- The scientific sounder – calibrated so quantifiable and comparable
- Operates at multiple frequencies (18, 38, 120, 200, 300kHz (same as fishermen)
- Frequency response helps determine species, but it's still largely reliant on expert knowledge
- Future is multibeam and broadband for greater discrimination near the bottom and more accurate sizing

Method

- The acoustic backscatter (the strength of the 'echo') is assigned to species
- The backscatter (target strength) of one fish is known (from experiments), so backscatter can be converted to numbers of fish.
- Trawl samples give the numbers and at size (age), so total number can be partitioned to size (age) groups.

International Herring Acoustic Survey 2018

[Resource: Why acoustic surveys go against the grain](#)

Fisheries independent

Tagging programmes

Use

Estimate population size and movement patterns

Survey principles

- $\text{Tags Released/Popn} = \text{Tags Recaptured/Catch}$
- Geolocation to reconstruct migration

Methods

- Tag fish and put them back – catch them again later
- Plastic, metal and RFID
- Simple data storage and advanced satellite
- Rewards required

Examples

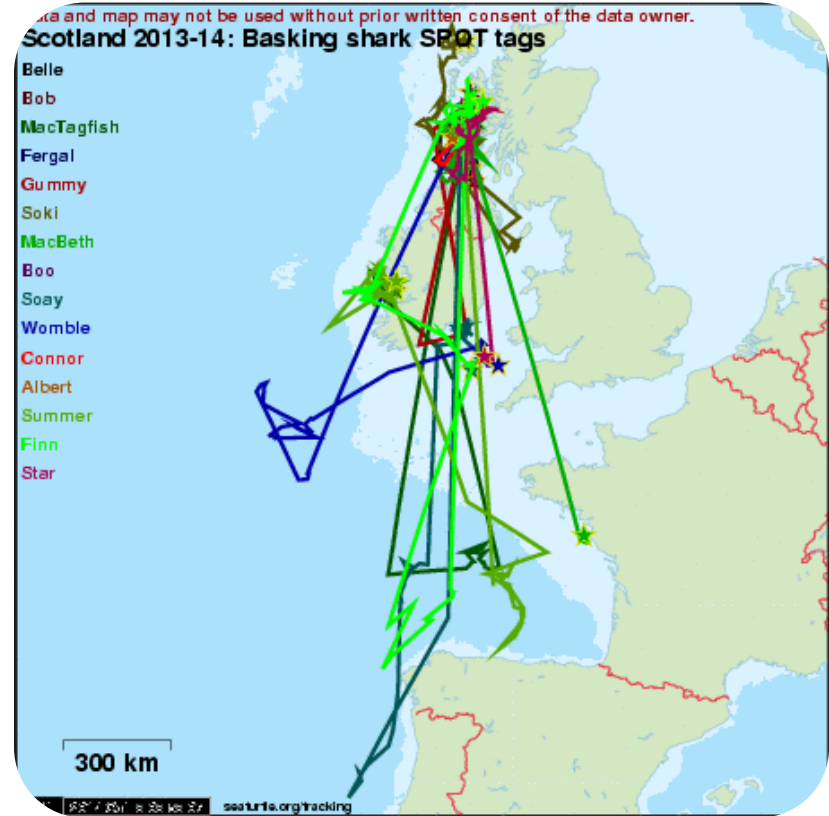

- Mackerel RFID and how it's being used in stock assessment
- Tracking behaviour – tuna, plaice – tidal stream transport, cod

Resource: How tagging programmes estimate fish abundance

Fisheries independent

Tagging programmes

How is the information used?

Where does it go?

Key information needs and its use

How many fish in the sea?

Setting fishing quotas and conservation measures.

How many get caught?

Estimating how many fish of each age group are in the sea and whether fishing pressure is sustainable.

The 'biology' - age, length and weight composition of the **population** and **catch**.

Where boats fish and how much (effort, catch per unit effort).

Translating goals for maintaining stocks in to the amount of fishing effort required for good average long-term catches. Indicators of the fishery performance and stock availability. Partitioning impacts by fleets.

Where fish are, where they go and why?

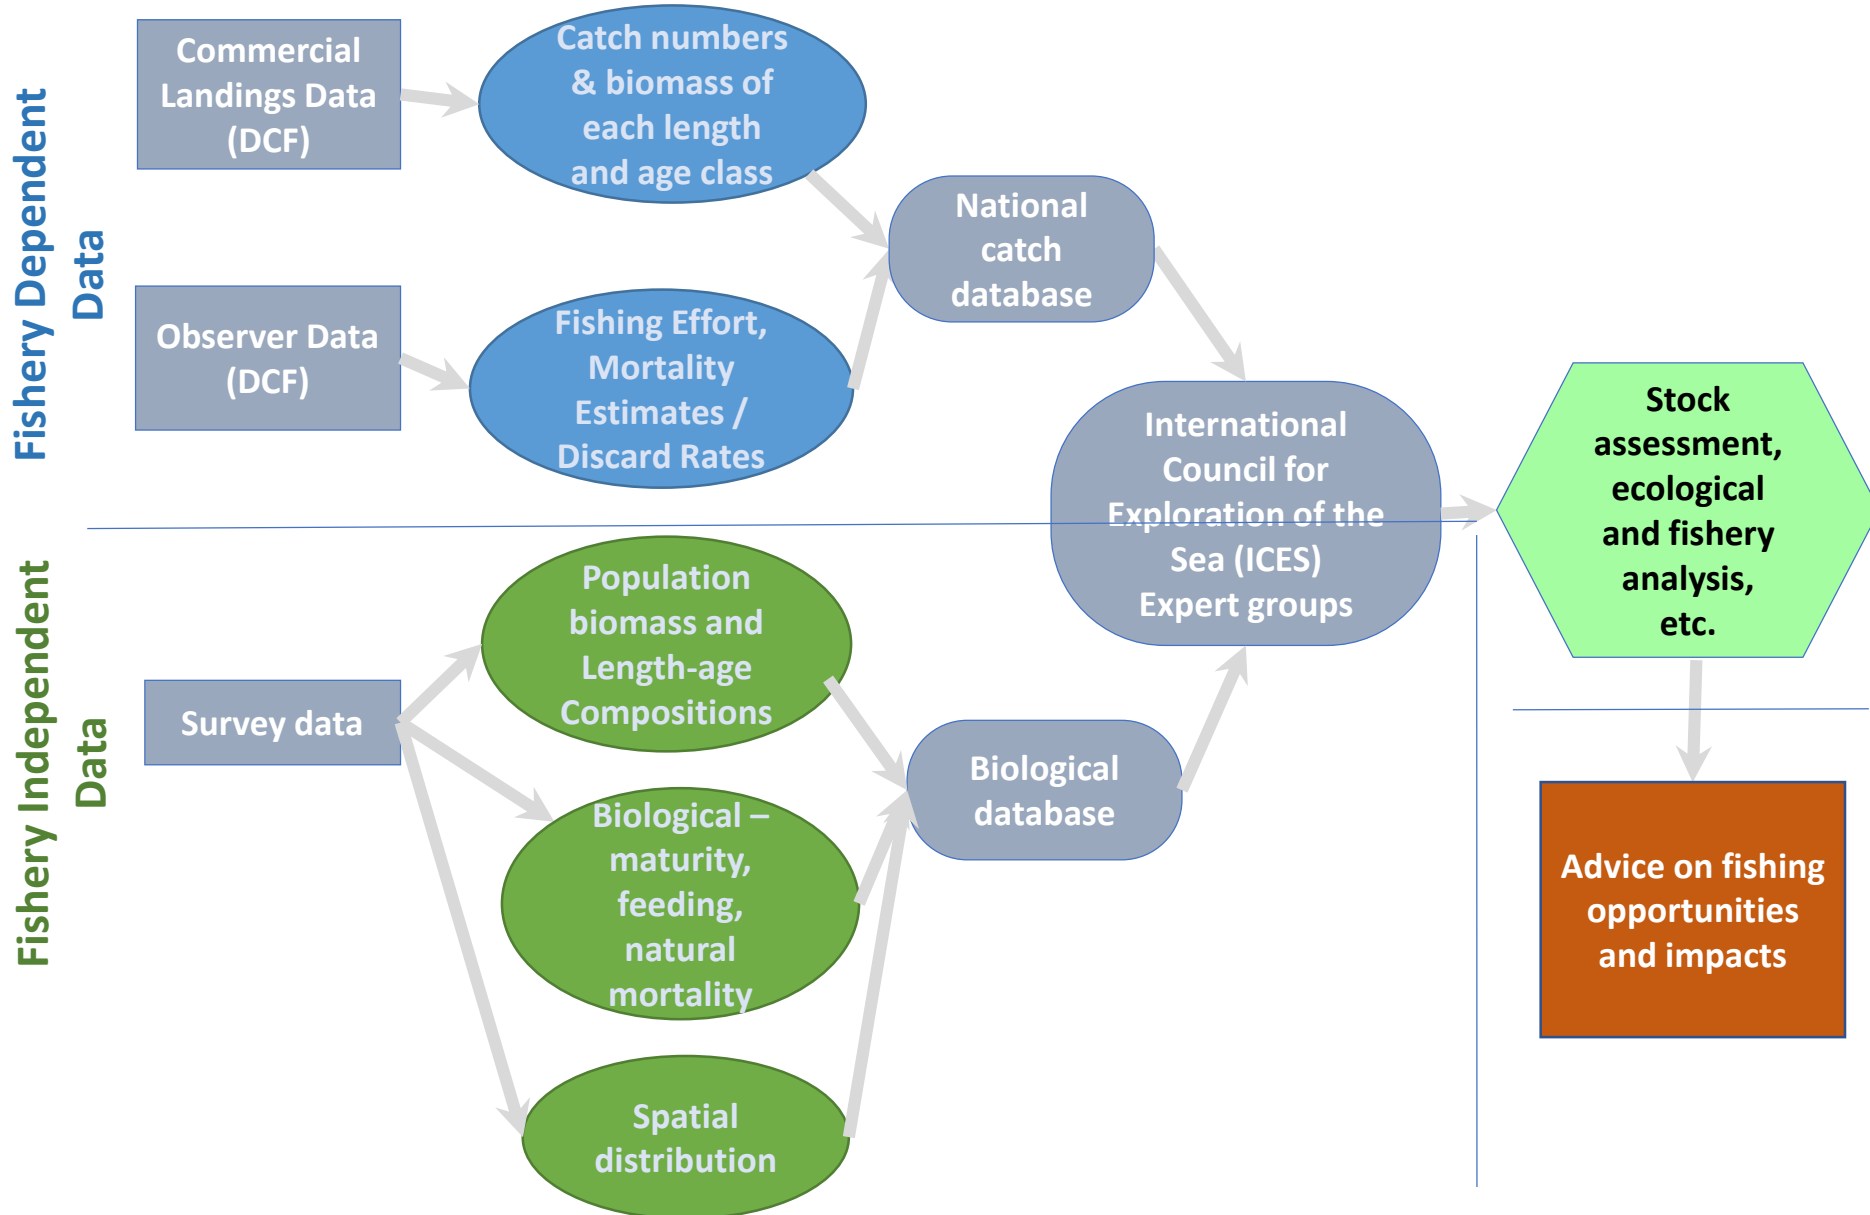

Fish migration and distribution patterns used in defining stocks, estimating abundance, fishing opportunities and spatial management measures.

How changes in the environment affect fish.

How changes in availability and productivity affect sustainable harvest rates and fishing opportunities

Fishery data flows

Fisheries dependent – summary takeaway

– meaning information **about catches and fishing activity** collected from the industry during the course of their normal operations.

Data needed	How it's collected	What it's used for
Landings (or Catch)	Logbooks, landing slips	How many fish of each age were removed from the population – required in stock assessment.
Discards	Logbooks, observer programmes, cameras	How many other fish were removed from the population (depending on survival)
Effort	Satellite monitoring (VMS), logbooks (fishing duration)	Fishing capacity and efficiency (catch per unit effort, CPUE). CPUE a proxy for changes in fish availability. Used to determine relative sources of mortality and sustainable harvest rates.
Biological data – lengths, weight and age in each group	Market sampling and Age reading from otoliths in the laboratory	Tracking the size and age composition of the population (cohorts), which is used in stock assessment to estimate the numbers and biomass of each age group. Also reveals biological and ecological changes, such as changes in growth due to feeding conditions.
Economic	Economic surveys	Economic performance of fleets, sectoral contribution national and local economy. Development objectives

Fisheries independent – summary takeaway

– meaning *information about the fish population and environment collected during scientific surveys, using sampling designs that provide the best estimate of stock density.*

Data type	How it's collected	What it's used for
Survey trawl catches	Bottom trawl surveys (Q1 and Q3) (Demersal or beam trawl) - Swept area method	Density index, catchability, population composition, distribution. Used in tuning stock assessment models.
Acoustic density (and trawl for ID/samples)	Calibrated split-beam scientific echosounders (Simrad EK60 or EK80)	Acoustic density at age. Particularly for pelagic species – herring, sprat. Abundance index for stock assessment models. Also changes in distribution patterns.
Burrow density for Nephrops	Underwater TV Cameras and image analysis processing	Relative abundance of Nephrops. Sex ratios.
Biological data – lengths, weight, age in each group	Survey catch sampling followed by lab analyses	Changes in the size and age composition of the population, proportion mature, growth rates. All used in stock assessments.
Tagging	Tagging – markers and trackers	Relative abundance estimates at age and estimating total mortality for use in stock assessment. Migration patterns and consequences for spatial management and zonal attachment.
Larval and egg counts	Various nets and samplers	Estimate abundance of that parent population (spawning sock size), determine spawning locations from timing, forecast likely recruitment
Environmental	Various physical and chemical sensors, water samplers and acoustic devices for seabed characteristics. Plus grabs and cores for sediments.	Relating patterns to environmental conditions. From population biology to ecological understanding necessary to make predictive models.

How can industry contribute?

Swept area survey game

RV I.C.Fish

Swept area survey game

RV I.C.Fish

The survey game – how it works

Three surveys, 1 each year

Design the survey – choosing where and how many sample hauls to take

You record the survey catches

Estimate how many fish in the sea

See how it went and do another survey the next 2 years

We compare approaches and results !

Swept area surveys: Tools

1. Density of the population in an area (the numbers per unit area). Often referred to as the Catch per unit effort (CPUE)

$$\text{Density}(CPUE) = \frac{\text{Survey catch}}{\text{Area swept by trawl}}$$

2. Total abundance of species in the area

$$\text{Abundance} = \text{Density} \times \text{Survey area}$$

Use the spreadsheet to design your survey and calculate the abundance

Fisheries independent

Swept area surveys: Methods

- Design – ways to divide up the sampling of the survey area efficiently and to get the best estimate even when unexpected things happen.
- Sampling protocols – reproducible so comparisons can be made
- Sampling the catch - biological information
- Raising the sub-sample to the sample catch
- Raising the survey catch to the total area
